PSM = positive surgical margin; HR = hazard ratio; NR = not reported; NS = not significant; BCR = biochemical recurrence; MP = metastatic progression; PCSM = prostate cancer-specific mortality; CI = confidence interval.

\* There were 281 patients with a solitary positive margin and 310 patients with multiple positive margins.

\* The p values were not reported; statistical significance was reached only in patients with high-grade tumors or extracapsular extension.

### Abstract

Positive surgical margin (PSM) extension reported as focal or non-focal/extensive is an important pathologic prognostic parameter after radical prostatectomy. Likewise, there is limited or no agreement on how to measure and what the best cut-off points to be used in practice are. We hypothesized that digital microscopy (DM) would potentially provide a more objective way to measure PSM and better define its clinical significance. To further our knowledge, we have evaluated PSM status in 107 laparoscopic radical prostatectomies using digital and conventional light microscopy (LM). DM evaluation detected three additional PSM cases, but no differences were seen (LM vs DM;  $p = 0.220$ ). Mean linear measurement correlated to biochemical recurrence (BR) (LM,  $p = 0.002$ ; DM,  $p = 0.001$ ). ROC analysis identified a cut-off point to assess linear measurement by LM (3.5 mm) or DM (3.2 mm), but only digital measurement was significant for BR-free survival. Our study also evaluated a cut-off  $\leq 3$  mm that was associated to BR using LM ( $p = 0.023$ ) or DM ( $p = 0.001$ ). Finally, the number of paraffin blocks bearing PSM correlated with BR ( $p < 0.001$ ) status with either LM or DM. In conclusion, DM produces similar data than LM but shows more accurate measurements. Reporting of PSM with score of  $\leq 3$  vs.  $> 3$  mm linear extent using LM (3.2 mm if digital microscopy is applied) might represent an important prognostic feature after radical prostatectomy. Alternatively, reporting the number of blocks with PSM 1 vs. 2 or more might also provide important prognostic data in practice.

Table 2 Patient and tumor characteristics for each patient having positive surgical margins in radical prostatectomy specimen

| No.             | Age (years) | pTN    | LM (mm) | LM single (mm) | blocks-LM | DM (mm) | DM single (mm) | Blocks-DM | Follow up (months) | BR | BR time (months) | GS | GG |

LN status lymph node status, GG grade group, LM light microscopy margins, cumulative length, LM single greatest single margin, light microscopy, DM digital margins, cumulative length, DM single greatest single margin, digital

<sup>a</sup> Mann–Whitney U test

**Fig. 3** Biochemical recurrence-free survival curves according to Kaplan-Meier plots and the log-rank test. Linear measurement by light microscopy (LM; **a**) was not significant ( $p = 0.11$ ). However, measurement by digital microscopy (DM; **b**) proved significant ( $p = 0.03$ ). **c, d** Differences using number of blocks (one versus more two or more) by light microscopy (block-LM) and digital microscopy (block-DM). Both, block-LM (**c**) and block-DM (**d**), proved statistically significant ( $p = 0.008$  and  $p = 0.01$ , respectively)

**Fig. 2** Receiver operating characteristic (ROC) assessment of cut-offs for PSM seen by light microscopy (LM) and digital microscopy (DM)

### Prediction of Organ-confined

**Prostate Cancer:** Incremental Value of MR Imaging and MR Spectroscopic Imaging to Staging Nomograms<sup>1</sup>

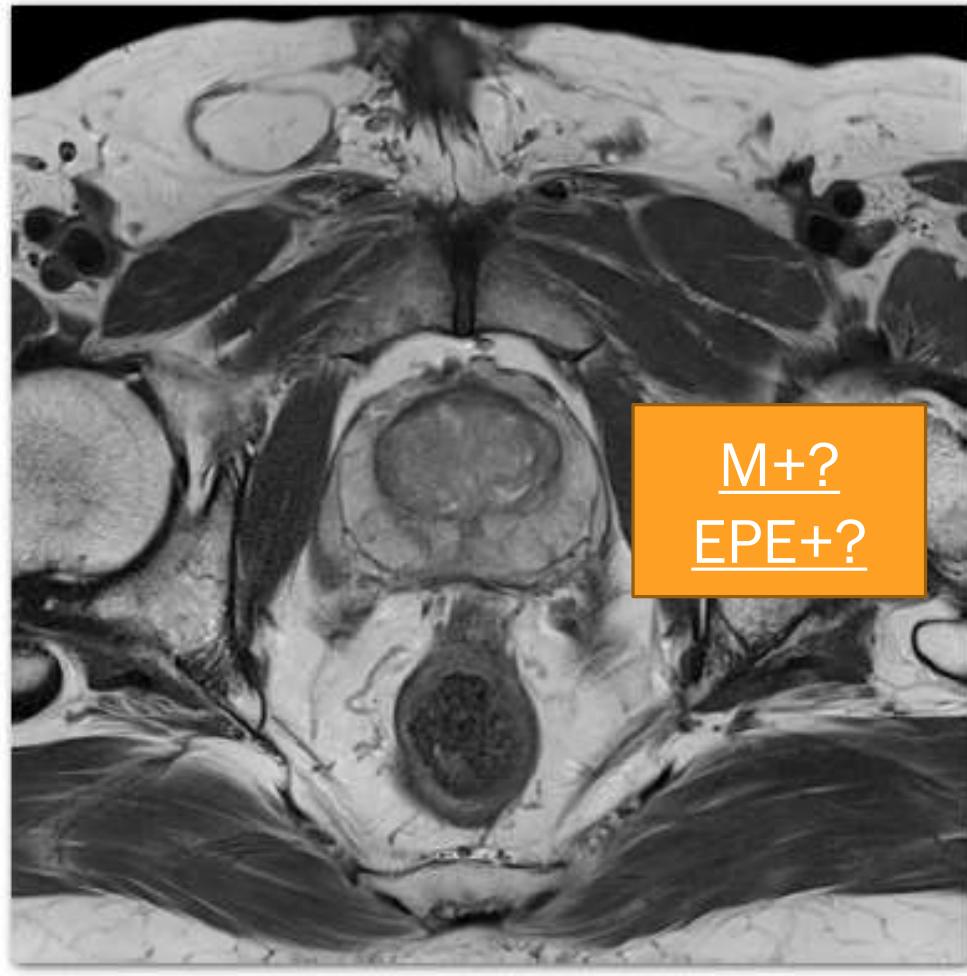

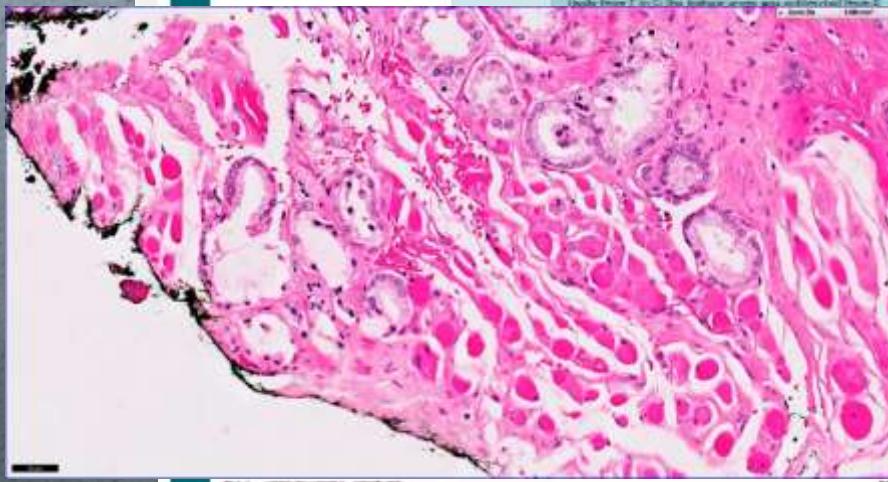

Ling Jiang, MD

Peter J. Scardino, MD  
Kurtin Kestle, MD, PhD

**Purpose:**

To assess independently the incremental value of sono-rectal coil magnetic resonance (MR) imaging and combined endorectal MR imaging/MR spectroscopic imaging to the staging nomograms for predicting organ-confined prostate cancer (OCP).

**Materials and Methods:**

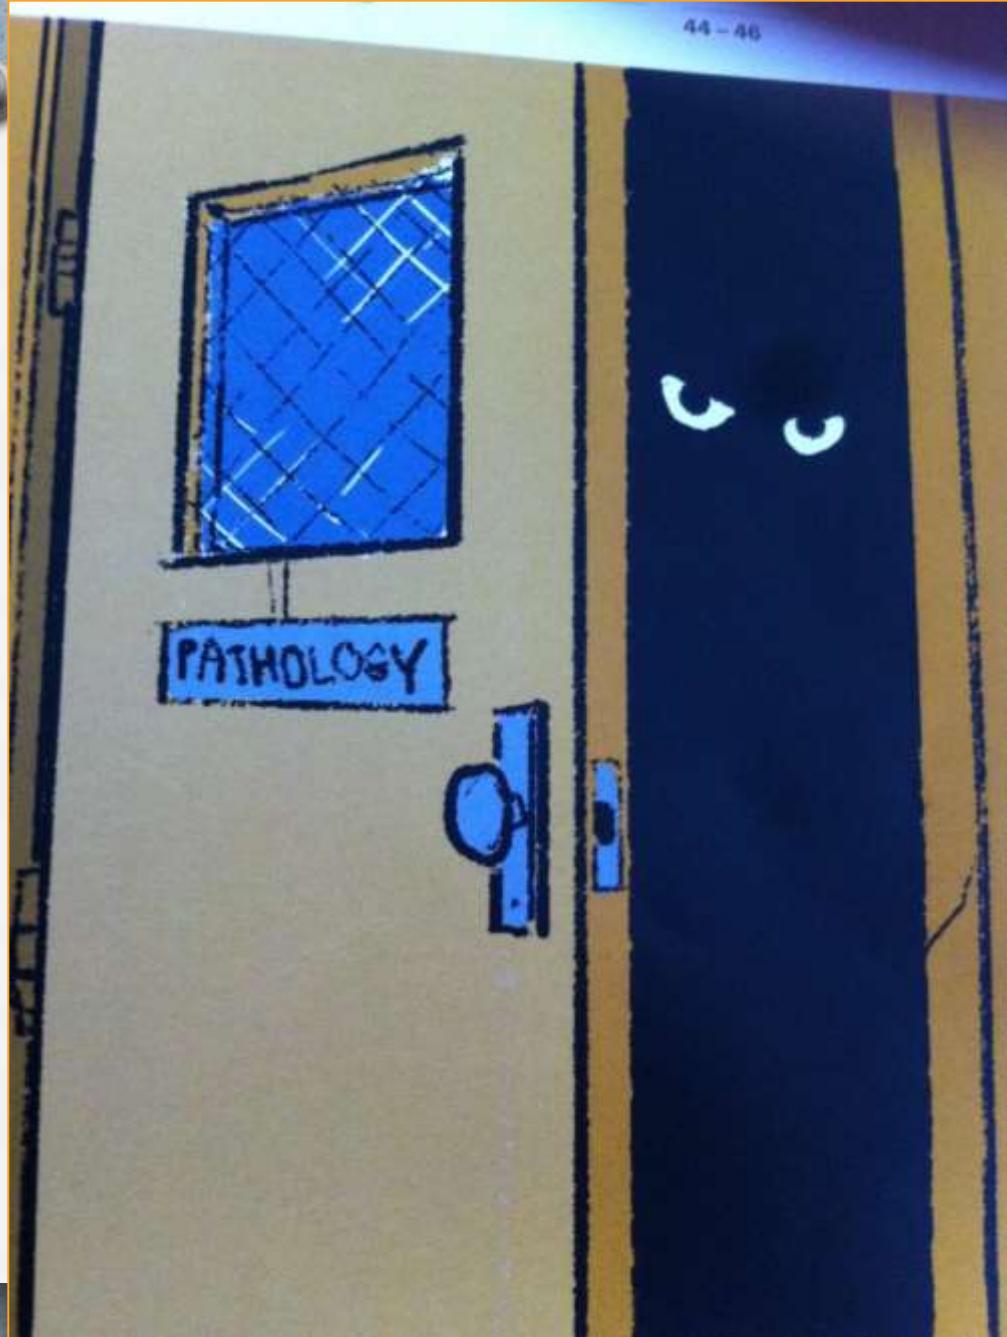

The institutional review board approved this IRBAA compliant study and issued a waiver of informed consent for review of the MR reports and clinical data. Between November 1, 1996, and November 1, 2004, 229 patients underwent endorectal MR imaging, and 300 underwent combined endorectal MR imaging/MR spectroscopic imaging before radical prostatectomy. Mean patient age was 58 years (range, 22–74 years). MR studies were interpreted prospectively by 12 radiologists who were informed of patients' clinical data. On the basis of the MR reports, the risks of extracapsular extension, seminal vesicle invasion, and lymph node metastasis were scored extraprostatic grade from 0 to 5. The outcome scores were as follows: clinical T1c, 0; clinical T1c/T2a, 1; clinical T2b, 2; clinical T2c, 3; clinical T2c/T3a, 4; clinical T3a, 5; pathologic T1c, 0; pathologic T1c/T2a, 1; pathologic T2b, 2; pathologic T2c, 3; pathologic T2c/T3a, 4; pathologic T3a, 5.

M+?  
EPE+?

# Conclusion

- En general, las mediciones totales (agregado longitudinal) tienen mejor poder discriminante que las mediciones del foco mayor individual.
- Patología digital mejora el reconocimiento y medición del M+ lo que tiene implicaciones clínicas.
- Patología digital mejora el reconocimiento y medición de la EPE, en particular del EPE radial, lo que tiene implicaciones clínicas.
